# Important!

## Please read this page carefully!

Although your uTracer is not directly connected to the mains, it generates dangerous and potentially lethal voltages. Please observe the following guidelines:

- Never touch the PCB when the high voltage LED is on!
- If you need to work on the circuit:
  1. First wait until the high voltage LED is off;
  2. Then switch off the power;
  3. Check with a DMM that the electrolytic caps are fully discharged
- When you test the circuit on the bench use the standoffs to distance the PCB from the table.
- Make sure that there are no loose wires or metal clipping lingering around or underneath the PCB.

Please note that even when the high voltage LED is off, the -85V and +130V grid supplies are still working !

## Tips and Tricks:

1. Bend the leads of the resistors in a sharp angle close to the body of the resistor.

2. Soldering the SMD transistor

Apply solder to one pad

Fix one leg of the transistor and adjust position

Solder the other small terminal

Apply some solder flux to the tab

Heat the tab with your soldering iron and add a bit of solder. When hot enough the solder will ready flow between the tab and PCB.

Note!

None of the transistors in the uTracer will get hot during operation, or conduct huge amounts of current. It is therefore sufficient to solder the tab only on one corner.

- 3 As usual, the pins of the PIC processor are at an angle so that the PIC doesn't fit directly in the 40 pin socket. The best way to adjust the angle of the pins is to hold the processor at the sides and correct the angle of 20 pins at once by bending them against a flat surface e.g. the table.

4. Make sure that you fully insert the PIC into the socket !! A not correctly (half) inserted PIC has given problems in a lot of instances causing faulty or erratic behavior. It requires the force of two thumbs to deeply and properly insert the PIC into the socket! (Picture taken from uTracer3+)

5. If you do not have a PCB holder, use a small box or something like that to make it easier to work on both sides of the PCBs

Always check the resistance value of each resistor with a multimeter before you assemble it onto the board.

When starting the construction of a new part, first read through the whole section and familiarize yourself with the photos. It can be that they clarify things that are otherwise perhaps difficult to understand from the text.

Some components may have been replaced by alternative types depending on availability from my supplier. Below you find a list of replacements used.

Component in circuit diagram	Replacement type(s)

## Part 1. Install the new PIC (if needed)

**Users that have a uTracer6 with PIC firmware V6.19 need to install the PIC with firmware version V6.29 that is supplied with the kit.**

The firmware detects if the extension board is present. If it is not present, the firmware works as before with the GUI V1. When the board is installed on start up the new functionality is enabled and the firmware only works with GUI V2 or higher.

- ❑ 1. Carefully remove the original PIC supplied with the uTracer6 kit make sure not to bend the pins and save the PIC to be able to return to the original firm ware.
- ❑ 2. Insert the new PIC with the updated firmware (see tips and tricks).
- ❑ 3. Test your uTracer6. Without the extension board mounted it should function exactly as before.

## Part 2. The graphical user interface (GUI) update

The positive grid extension board requires GUI V6.2 or higher, is can be downloaded from:

[https://www.dos4ever.com/uTracer3/uTracer\\_6p2.zip](https://www.dos4ever.com/uTracer3/uTracer_6p2.zip)

(note that there is an underscore between uTracer and 6p2)

It is assumed that GUI V6.1 is already installed and working

- ☐ 1. Start the old GUI (the one you are using now) and note down the calibration values.
- ☐ 2. Download the zip file containing V6.2 (or higher) and unzip it.
- ☐ 3. Move the executable to a folder from where you want to run the GUI.
- ☐ 4. Double click the executable to start the GUI.
- ☐ 5. On startup automatically a new calibration file will be created.
- ☐ 6. Open the calibration form and enter the calibration values recorded in step 1.
- ☐ 7. Save the calibration file.

Without the extension board you can still use the GUI V6.1

## Part 3. Positive grid boost converter grid switch

- ☒ 1. IC1, LTC6090
- ☒ 2. IC2, OPA2189
- ☒ 3. D5, BAT74
- ☐ 4. T1, FQD12N20LTM
- ☐ 5. R1, 200k
- ☐ 6. R2, 4k7
- ☐ 7. R7, 33 ohm
- ☐ 8. R6, 4.7 ohm
- ☐ 9. D1, diode UF4007 note polarity !
- ☐ 10. D2, diode UF4007 note polarity !
- ☐ 11. D3, diode UF4007 note polarity !
- ☐ 12. D7, zener diode BZT03C130 note polarity !
- ☐ 13. L1, 220 uH
- ☐ 14. C1, 47uF / 160V note polarity !
- ☐ 15. C2, 47uF / 160V note polarity !
- ☐ 16. R17, 1k
- ☐ 17. R18, 1k (note that on the PCB the value is missing)
- ☐ 18. R19, 1k (note that on the PCB a value of 180 ohm is indicated)
- ☐ 19. D6, diode UF4007 note polarity !
- ☐ 20. L1, red LED note polarity ! → A = anode = long pin
- ☐ 21. L2, red LED note polarity ! → A = anode = long pin
- ☐ 22. T9, BC548 note orientation !
- ☐ 23. REL1, 12V miniature pcb relais.

Overview of the PCB after step 4. Note that the shape and color of components can vary depending on availability.

## Part 4. The board-to-board connector

Installation of the board-to-board connector requires a bit of fiddling, but this is the solution I used. Feel free to use a solution that suits you better.

- 1. Install on the main board the two threaded standoffs.

- 2. Install one of the two 20 pin male pin headers on the extension board as shown below.

**Note that the long pins are inserted into the PCB!**

Solder the pins from the backside of the PCB and make sure the solder fills the pads.

- 3. Install on second 20 pin male pin header on the main board.

- 4. Press the 20 pin SIL socket on the pin header of the main board.

- 5. Place the extension board on the standoffs and loosely tighten the two M3 bolts.

- 6. Make sure the pins between the two boards are neatly aligned and then solder the pin 1 and 20 of the pin header to the single in line socket underneath.

- 7. Carefully remove the extension board from the main board and solder the remaining 18 pins.

## Part 5. testing the boost converter

Place the extension board on the main board.

Apply power to the main power.

Immediately LED 2 should turn on and then within a few seconds LED 1 (as well as the relay) will blink twice and then remain off. When this happens it is a sign that all three boost converters, the -15V and -85V on the main board, as well as the 120 V on the extension board, are all function correctly and have reached their setpoint values.

Check the voltages on the cathodes of D1 and D2 with respect to ground, they both should be between 120 – 130 V.

Do not slip with measurement probe!

## Part 6. Completion of the circuit

- ☐ 1. R3, 1k
- ☐ 2. R5, 1k
- ☐ 3. R11, 1k
- ☐ 4. R4, 10k
- ☐ 5. R8, 10k
- ☐ 6. R13, 10k
- ☐ 7. R15, 4k7
- ☐ 8. R16, 4k7
- ☐ 9. R9, 47k
- ☐ 10. R14, 47k
- ☐ 11. R10, 1M
- ☐ 12. R12, 4.7 ohm
- ☐ 13. D4, zener diode BZT03C130 note polarity !
- ☐ 14. C4, 150 nF
- ☐ 15. C5, 150 nF
- ☐ 16. C3, 150 pF
- ☐ 17. P1, 50k potentiometer
- ☐ 18. T5, BC548 Note orientation !
- ☐ 19. T6, BC548 Note orientation !
- ☐ 20. T3, KSP44 Note orientation !
- ☐ 21. T4, KSP44 Note orientation !
- ☐ 22. T2, KSP44 Note orientation !
- ☐ 23. T7, KSP44 Note orientation !
- ☐ 24. T8, KSP44 Note orientation !
- ☐ 25. place 2 pin pin-header J1
- ☐ 26. place 2 pin pin-header J2
- ☐ 27. place 2 pin pin-header J3

- ☐ 28. place a jumper on pin-header J1
- ☐ 29. place a jumper on pin-header J2
- ☐ 30. place the PCB terminal block

The extension board after completion

- ❑ 31. Install the extension board on the main board.
- ❑ 32. Connect the grid output of the main board with the grid input of the extension board (see below).

The grid output of the extension board is now the new grid connection of your uTracer. It will switch automatically between the negative grid supply on the main board and the positive grid supply on the extension board.

On the next pages the calibration procedure is described. It consists of 5 steps. Please note that during the calibration high voltages are present on the board. Always switch off power when you need to change something to the wiring or need to place or remove jumpers !

## Part 7. Calibration 1 – offset adjustment

- ❑ 1. Make sure the jumpers are installed as follows:
  - Jumper 1 = installed
  - Jumper 2 = installed
  - Jumper 3 = removed
- ❑ 2. Connect a 10k resistor between the grid terminal on the extension board and the cathode terminal on the main board (see below).

- ❑ 3. Switch your uTracer on.
- ❑ 4. Measure the voltage between the slider of P1 and ground.

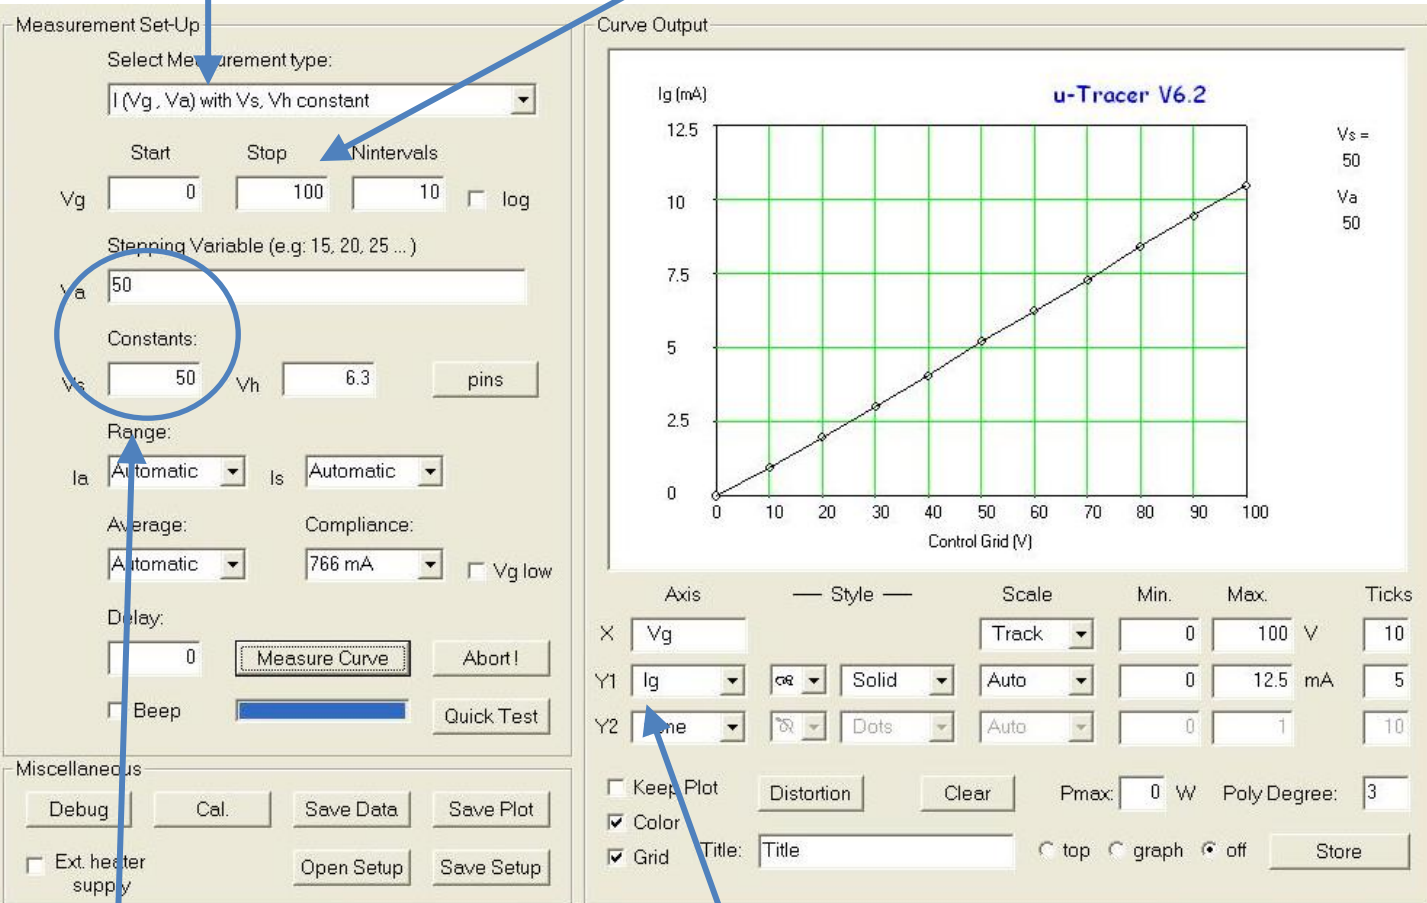

There is no need to remove the board of for this. The slider voltage can be probed on R8 (do not slip with your test pen).

- ☐ 5. Adjust P1 so that the voltage is approximately 0V.
- ☐ 6. Select the measurement and settings as shown below:

$I(V_g, V_a)$  with  $V_s, V_h$  constant

100 V

Select relatively safe voltages of 50 V

Make sure to select as plotting variable Ig

Please note that during the measurement High voltages are present on both boards!

- ☐ 7. Start a measurement.
- ☐ 8. Now adjust P1.
- ☐ 9. Repeat steps 7 and 8 until the measurement is a nice straight line going through (0,0) . See figures on the next page.

Adjust P1 such that the voltage on its slider becomes more **negative**.

Perfect!

Adjust P1 such that the voltage on its slider becomes more **positive**.

offset

## Part 8. Calibration 2 – voltage adjustment

- ❑ 1. Make sure the jumpers are installed as follows:  
Jumper 1 = installed  
Jumper 2 = removed !!!!! ←  
Jumper 3 = removed
- ❑ 2. Connect a 100K resistor (value not critical) between grid and cathode terminals.
- ❑ 3. Connect you DVM (digital voltmeter) between grid and cathode terminals, see below:

- ❑ 4. Select the measurement shown below (all other settings standard):

Measurement Set-Up

Select Measurement type:

$I(V_a, V_g)$  with  $V_s, V_h$  constant

	Start	Stop	Nintervals	
$V_a$	2	50	10	<input type="checkbox"/> log

Stepping Variable (e.g. 15, 20, 25 ...)

$V_g$  90

Constants:

$V_s$	50	$V_h$	6.3	pins
-------	----	-------	-----	------

- ☐ 5. Open the calibration form.
- ☐ 6. Start the measurement.
- ☐ 7. Read out the grid voltage from your DVM.
- ☐ 8. If the grid voltage is not 90 V, adjust the “Vgrid +” slider (below) and repeat step 6 till 8 until the voltage reads 90 V.

- ☐ 9. Save the calibration file.
- ☐ 10. **Place Jumper J2 back !!**

## Part 9. Calibration 3 – current (high scale) adjustment

- ❑ 1. Make sure the jumpers are installed as follows:
  - Jumper 1 = installed
  - Jumper 2 = installed
  - Jumper 3 = removed
- ❑ 2. Connect a 1K resistor (preferably a 1% type) between grid and cathode terminals.
- ❑ 4. Select the measurement show below (all other settings standard):

The screenshot shows two windows from a software interface. The 'Measurement Set-Up' window on the left contains the following settings: 'Select Measurement type:' is set to 'I (Vg, Va) with Vs, Vh constant'; 'Start' is 0, 'Stop' is 100, and 'Intervals' is 10; 'log' is checked; 'Stepping Variable (e.g: 15, 20, 25 ...)' is set to 50; 'Constants:' shows 'Vs' as 50 and 'Vh' as 6.3 with a 'pins' button; 'Range:' shows 'Ia' and 'Is' both set to 'Automatic'; 'Average:' is 'Automatic' and 'Compliance:' is '766 mA'; 'Delay:' is 0; 'Beep' is unchecked; and buttons for 'Measure Curve', 'Abort!', and 'Quick Test' are at the bottom. The 'Curve Output' window on the right shows a plot of 'Ig (mA)' on the y-axis (0 to 100) against 'Vg' on the x-axis. The y-axis has horizontal grid lines at every 10 units. Below the plot, the 'Axis' section shows 'X' as 'Vg', 'Y1' as 'Ig' (highlighted with a blue arrow), and 'Y2' as 'none'. A text annotation with a blue arrow points to the 'Y1' dropdown, stating: 'Be sure to select the grid current as the plot variable'.

- ❑ 5. Switch your uTracer on.
- ❑ 6. Run a measurement.

- 7. Place the cursor on the measured line somewhere in the area of 90V. Read out the current (I) in mA and the voltage (V) in V.

- 8. Calculate  $R = 4.7 * (I / V)$  with I in mA  
So, in this example  $R = 4.7*(88.7/90.2) = 4.62$  (ohm)
- 9. Open the calibration form and enter the corrected value for Rg.

Current sense resistors

	Ra	Rs	Rg	
V6	4.7	4.7	4.7	Ohm
Spare	4.7	4.7	4.7	Ohm

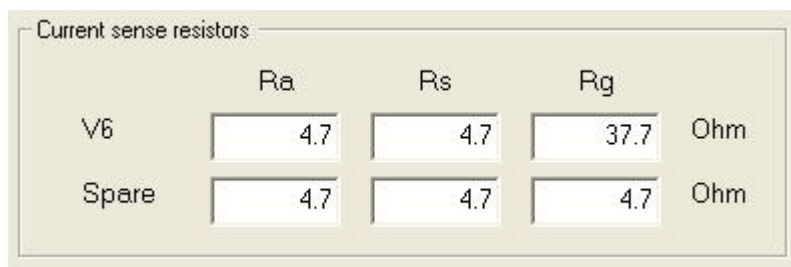

here:

- 10. Save the calibration form
- 11. Close the GUI and start the GUI again to activate the new value for Rg
- 12. Run the measurement again to verify that at 90V the current measured is indeed 90mA

Note down the value for Rg (100mA) range:

## Part 10. Calibration 4 – current (low scale) adjustment

- ☐ 1. Make sure the jumpers are installed as follows:  
Jumper 1 = removed !!!!! ←  
Jumper 2 = installed  
Jumper 3 = removed
- ☐ 2. Connect a 10K resistor (preferably a 1% type) between grid and cathode terminals.
- ☐ 4. Start the GUI and open the calibration form.
- ☐ 5. Change Rg to 37.7 ohm.

	Ra	Rs	Rg	
V6	4.7	4.7	37.7	Ohm
Spare	4.7	4.7	4.7	Ohm

- ☐ 6. Close the GUI and start it GUI again to activate the new value for Rg.
- ☐ 7. Run the same measurement as in Section 9.
- ☐ 8. Place the cursor on the measured line somewhere in the area of 90V. Read out the current (I) in mA and the voltage (V) in V.  
The current measured should be approximately 9 mA.
- ☐ 9. Calculate  $R = 37.7 * 10 * (I / V)$  with I in mA .
- ☐ 10. Open the calibration form and fill in this corrected value for Rg.
- ☐ 11. Save the calibration form.
- ☐ 12. Close the GUI and start the GUI again to activate the new value for Rg.
- ☐ 13. Run the measurement again to verify that at 90V the current measured is indeed 9 mA.

Note down the value for Rg (10 mA) range:

Depending on the current range you want to use place jumper J1 or remove it and change the value for  $R_g$  in the calibration form accordingly. Make sure to save the calibration file and shut down and start the GUI to make the changed value for  $R_g$  active.

## Part 11. Calibration 5 – negative grid bias range

Since the negative grid bias calibration range has been increased in the new GUI, it is unfortunately necessary to recalibrate this negative grid section.

- ☐ 1. Temporarily remove the extension board.
- ☐ 2. Temporarily remove jumper J2 **on the main board.**
- ☐ 3. Connect a DVM between the grid and cathode terminals of the uTracer.
- ☐ 4. Run the same measurement as in part 8 but now with  $V_g = -90V$ .
- ☐ 5. Change  $V_{grid-}$  in the calibration form if needed
- ☐ 6. Re-run the measurement until the measured until the measured grid voltage equals  $-90V$ .
- ☐ 7. Switch off the power.
- ☐ 8. Again install jumper J4 **on the main board.**
- ☐ 9. Re-install the extension board.
